

Exhibit 2
Flood Control Structures

The project site was originally a flood irrigated agricultural field. The flood control system consists of a channel that runs east to west along the northern property boundary and a smaller collector channel that runs south to north along the entire width of the effective floodplain on the west side of Murphy Road. A flow constricting structure is located within the channel downstream of the Murphy Road crossing and is used to maintain the historic flow breakout to the north. The project may be accessed from Honeycutt Road to Murphy Road.
